## 1 Supplementary Information: Verdict-style prompts induce moral over-resolution in large language models

This Supplementary Information provides additional methodological detail, source-data references and reproducibility documentation for the Article. It is organized to support review of the prompt construction, source-community distribution processing, target allocation, model roster, parsing and validity rules, endpoint definitions, robustness checks, secondary analyses, Extended Data items and public/restricted material boundaries. Large exported tables are cited through source-data paths rather than reproduced in full.

### 1.1 Supplementary Note 1: Prompt templates, response schemas and hashes

This note supports reproducibility of the prompt-format comparisons. The prompt templates, response schemas, label schema, prompt modes and hashing utilities are code-defined in:

- `src/prompts/prompt_templates.py`
- `src/prompts/schemas.py`
- `src/prompts/prompt_hashing.py`
- `src/protocol/label_schema.py`
- `src/protocol/prompt_modes.py`
- `src/utils/hashing.py`

The frozen code-file hashes used to identify these prompt and schema components are:

| Component                       | SHA-256                                                          |
|---------------------------------|------------------------------------------------------------------|
| src/prompts/prompt_templates.py | 7f673dd3ca14d3780b53c05d16b67df2af98c7c750fc97256938a9976f32599b |
| src/prompts/schemas.py          | 58a3c91e42cb8264253f1c705a6c6d2162405fc6167e61c9ec28f5eefef02619 |
| src/prompts/prompt_hashing.py   | 9153ce8e1a34cfd2fb897343eaecb4b7e327460b3c4c101535bc2306b80ee491 |
| src/protocol/label_schema.py    | d743eee461e80b7b4cafcbabf8e1a1b0db15bcc98f29f7d467824b01a581369  |
| src/protocol/prompt_modes.py    | f6a2f157a1d120677a385db4aea022621e0dd816700c57f853561469d3735bce |
| src/utils/hashing.py            | 772528eb9234091835c9b9cd6f38dbc22384649c754b05645d248e78426cc707 |

The canonical label schema is `scruples_five_label_v1`, with five labels: `author`, `other`, `everybody`, `nobody` and `info`. The prompt modes are distribution mode, descriptive verdict/agreement mode, normative verdict mode, sampling mode, paraphrase generation, paraphrased distribution mode and paraphrased descriptive verdict mode. Recognition-audit prompt and schema definitions are present in the code release as unused definitions; they were not executed, analysed or used to support any claim, and no formal recognition audit was run for the final 50k analysis.

Distribution-mode outputs require `label_probabilities` and `most_likely_label`. Descriptive verdict/agreement outputs require `chosen_label` and `estimated_source_community_agreement`. Normative-verdict outputs require `chosen_label` and `moral_certainty`. Sampling-mode outputs require `chosen_label`. Schemas use fixed label enumerations and disallow additional top-level properties where applicable.

Stable schema hashes are: distribution mode, 62225e53095e01dded2b558b031b5d246c3dfcf403d660a0f12ef6c5d074f9ff; descriptive verdict/agreement mode, 75cefb0c22603127c15e101628358e4e64a7462ee662080e37667ca439077284; normative verdict mode, b61f82be27531ac964f7291b0fc2e73a3e045f7561965f35d84da0205324554b; sampling mode, 6a31e2aad4d6a2d3a852b213d99ad09c7c2bbbf716e8e3ee9402d61da7c0ed68; recognition audit, c0cbb3f41df3ee3f2e4339ecd0ecbe2224cba33069df3935b47ac889e4bce44d; paraphrase generation, 29c4483a9f7a7677861cb301f35536d35ac9f88bc9e69ae30e2ca945d970b826; paraphrased distribution mode, 62225e53095e01dded2b558b031b5d246c3dfcf403d660a0f12ef6c5d074f9ff; and paraphrased descriptive verdict/agreement mode, 75cefb0c22603127c15e101628358e4e64a7462ee662080e37667ca439077284. The recognition-audit hash is listed only because the schema definition is part of the code release; it does not indicate collection or analysis of recognition-audit outputs.

Prompt hashes are SHA-256 hashes of rendered prompt strings. Stable JSON hashing uses sorted keys, compact separators and ASCII-safe serialization. Rendered prompt hashes were computed after inserting item text and randomized label order. Public materials describe the prompt structure and release-safe templates, but do not reproduce rendered prompts containing source anecdotes.

Release-safe prompt skeletons are shown below. They use placeholders for source anecdotes, paraphrased source anecdotes, randomized label order and response schemas; rendered prompts containing source anecdotes are not reproduced. Full template implementation details are provided in `src/prompts/prompt_templates.py`, with response schemas in `src/prompts/schemas.py`; file paths are relative to the released repository/archive root. In the rendered prompts, the category block combines `{randomized_label_order}` with the corresponding `{label_definitions}`.

Distribution mode:

You will read a real-life ethical situation.

Task: Estimate how source-community judges would distribute their judgments

→ across the available categories, using the category definitions exactly as  
→ shown.

Return only JSON with top-level fields: `label_probabilities`,

→ `most_likely_label`.

Required JSON shape: `{response_schema}`

Constraint: probabilities are decimals from 0.0 to 1.0 and sum to 1.0.

Categories: `{randomized_label_order}` + `{label_definitions}`

Situation: `{situation_text}`

Descriptive verdict/agreement mode:

You will read a real-life ethical situation.

Task: Choose the best judgment category, then estimate what proportion of

→ source-community judges would agree with that chosen category.

Return only JSON with top-level fields: chosen\_label,  
↪ estimated\_source\_community\_agreement.  
Required JSON shape: {response\_schema}  
Constraint: agreement estimate is a decimal from 0.0 to 1.0.  
Categories: {randomized\_label\_order} + {label\_definitions}  
Situation: {situation\_text}

Repeated-sampling mode:  
You will read a real-life ethical situation.  
Task: Choose the best judgment category.  
Return only JSON with top-level field: chosen\_label.  
Required JSON shape: {response\_schema}  
Categories: {randomized\_label\_order} + {label\_definitions}  
Situation: {situation\_text}

Normative-certainty mode:  
You will read a real-life ethical situation.  
Task: Choose the morally best judgment category, then report how morally  
↪ certain you are in that judgment.  
Return only JSON with top-level fields: chosen\_label, moral\_certainty.  
Required JSON shape: {response\_schema}  
Constraint: moral-certainty estimate is a decimal from 0.0 to 1.0.  
Categories: {randomized\_label\_order} + {label\_definitions}  
Situation: {situation\_text}

Paraphrase-generation mode:  
Task: Rewrite the ethical situation so wording, phrasing and distinctive  
↪ surface details are changed while preserving the same basic moral  
↪ situation, roles and available judgments.  
Constraint: do not add new morally relevant facts.  
Return only JSON with top-level field: paraphrased\_situation.  
Required JSON shape: {response\_schema}  
Situation: {situation\_text}

Paraphrased distribution and paraphrased descriptive verdict/agreement modes:  
Same template structure as distribution mode and descriptive verdict/agreement  
↪ mode, respectively.  
Categories: {randomized\_label\_order} + {label\_definitions}  
Situation: {paraphrased\_situation\_text}  
Return: {response\_schema}

Item subset selection and label-order assignment used seed 20260615. For each prompt assignment, the local label-order seed was derived as the first 16 hex characters of the stable hash of [seed, item\_id, model\_id, mode, sample\_id], converted to an integer and passed to Python's random.Random; the resulting label order and assignment hash were stored with each request. The post-50k manifest reports 120 unique label orders in the paraphrase audit.

## 1.2 Supplementary Note 2: Dataset preprocessing, label schema and source-community distributions

This note documents how SCRUPLES Anecdotes were converted into the source-community reference distributions used by the endpoints. The five canonical labels were retained in the

primary analysis, including `info` for not enough information/cannot tell. Retaining `info` preserves the observed five-label disagreement structure rather than forcing uncertain cases into one of the four substantive blame labels.

Source-community vote counts were converted to primary source-community distributions using Jeffreys-smoothed Dirichlet posterior means with  $\alpha = 0.5$ . Raw proportions and Laplace smoothing with  $\alpha = 1.0$  were retained as robustness checks.

SCRUPLES judgments are treated as source-community reference distributions. They are not treated as authoritative moral labels, universal norms, representative population estimates or deployment-ready normative standards.

### 1.3 Supplementary Note 3: Sampling, disagreement bins and target allocation

This note supports interpretation of the primary and secondary endpoint subsets. The final analysis uses the frozen 50k analysis with 47,500 target calls and 47,432 primary-valid outputs. The core cross-format item allocation is 350 high-consensus items, 400 moderate-consensus items, 750 low-consensus items and 500 diffuse/no-clear-consensus items.

Disagreement bins are based on top-label source-community support:

- high consensus: top-label support at least 0.80;
- moderate consensus: top-label support at least 0.65 and less than 0.80;
- low consensus: top-label support at least 0.50 and less than 0.65;
- diffuse/no-clear-consensus: top-label support less than 0.50.

Low-consensus items are the primary confirmatory subset. Diffuse/no-clear-consensus items are secondary and remain separate from the primary endpoint definition. Low-consensus plus diffuse/no-clear-consensus aggregates, when reported, are descriptive divided-item summaries rather than primary endpoints.

For the repeated-sampling component, each item-model pair received ten separate fresh forced-choice calls at temperature 0.0. Sampling compression summarizes diversity across these repeated calls under the recorded prompt and label-order randomization protocol, not stochastic sampling from an internal model distribution.

### 1.4 Supplementary Note 4: Model roster, API parameters and collection windows

This note provides provenance for the evaluated model roster and request settings. The amended frozen roster contains five models: `claude-sonnet-4-6`, `deepseek/deepseek-v3.2`, `gpt-5.5`, `grok-4.3` and `qwen/qwen3.7-max`. Each model has 9,500 target calls. API routes, first and last call timestamps, temperature and top-p fields are reported in `post_run/analysis_exports/50k/manuscript_tables/table_model_roster_50k.csv`.

Production calls used single-turn request payloads with one rendered prompt per call. The verdict/agreement request did not include the model's distribution-mode response. Request JSON, response-schema field, rendered prompt hash, label order, timestamps, provider route and retry count were stored for each call. The provider wrapper allowed up to five HTTP attempts for retryable transport or server/rate-limit failures; the final 50k run recorded 0 API errors, 0 terminal failures and retry rate 0.0.

Provider/route fields are provenance fields. They are not used for inferential cross-provider or model-lineage comparisons. Model snapshot dates are not inferred beyond the recorded first and last call timestamps.

## 1.5 Supplementary Note 5: Parsing, validity, repair fields and exclusions

This note supports the validity and exclusion rules used before endpoint computation. Strict schema enforcement was used where supported. Otherwise, JSON was extracted and validated against required fields and ranges. Outputs were excluded from primary analyses if they were empty, invalid JSON, out of range, outside probability-normalization tolerance, missing required fields, refusals, off-schema labels or terminal/API failures without a valid response.

For distribution-mode outputs, all five label probabilities had to be castable to floats and within the closed interval  $[0, 1]$ . Probability vectors were accepted when their total fell within the inclusive interval  $[0.99, 1.01]$ . Accepted vectors whose totals differed from 1.0 by more than  $1e-12$  were renormalized to sum to one before downstream use. Vectors with totals below 0.99 or above 1.01 were marked as probability-sum errors and excluded from primary analyses. The  $1e-12$  threshold is not the exclusion tolerance; it only determines whether an already accepted near-sum vector is renormalized.

Final validity summary:

- target calls: 47,500;
- primary-valid outputs: 47,432;
- strict-schema outputs: 38,790;
- extracted-JSON outputs: 8,642;
- probability-out-of-bounds outputs: 52;
- probability-sum errors: 10;
- invalid-JSON outputs: 4;
- empty responses: 2;
- refusals: 0;
- off-schema labels: 0;
- repair attempted: 0;
- repair successful: 0.

Repair fields were tracked, and the final 50k analysis contained no repaired outputs.

## 1.6 Supplementary Note 6: Endpoint definitions, bootstrap inference and multiplicity adjustment

This note defines the three endpoints used to test cross-format uncertainty transfer. Agreement surplus is the verdict-mode estimated source-community agreement minus source-community support for the model’s chosen label. Distribution-agreement gap is the verdict-mode estimated agreement minus the same model’s distribution-mode probability for that verdict label. Sampling compression is source-community entropy minus repeated-sample model entropy on the five-label scale in bits.

The distribution-agreement gap is a within-model endpoint: it compares the same model, item and verdict-selected label across two elicitation formats. It tests output coherence and does not require the model’s distribution-mode estimate to perfectly match the source-community distribution.

Primary inference uses item-cluster bootstrap confidence intervals with 2,000 bootstrap iterations and seed 20260621. For bin-specific estimates, each bootstrap replicate resampled item IDs with replacement within the bin and retained all relevant model/prompt rows associated with the resampled items. This item-level clustering avoids treating item-model rows as fully independent observations. One-sided positive-effect bootstrap P values are Holm-adjusted across the three low-consensus primary endpoints. With 2,000 bootstrap iterations, the low-consensus Holm-adjusted values are reported as  $P = 0.0015$ .

## 1.7 Supplementary Note 7: Robustness checks

This note lists robustness checks that address likely reviewer concerns about parsing, source-community distribution construction, annotation density, **info** responses and model-level dependence. Robustness outputs include strict-valid-only analyses, raw/Jeffreys/Laplace source-community distribution checks, high-annotation-only checks, **info**-majority exclusion, high-**info** exclusion, leave-one-model-out summaries and model-level endpoint summaries. These checks support the direction of the main findings while preserving the primary status of the low-consensus endpoint definitions.

Mixed-effects input rows are provided for transparency. They do not constitute reported mixed-effects analyses, and no mixed-effects model result is reported.

## 1.8 Supplementary Note 8: Paraphrase audit and contamination limitation

This note describes the role and limits of the paraphrase component. The paraphrase audit uses paraphrased versions of a stratified item subset and is reported as aggregate surface-form evidence. Because original-vs-paraphrase matched coverage is limited, paraphrase results should not be framed as a definitive paired paraphrase test.

The paraphrase audit contained 2,500 target calls and 2,495 valid outputs. Within the limited matched original-vs-paraphrase overlap, coverage was 29 low-consensus rows and 15 diffuse rows; chosen-label stability was 0.655 in low-consensus rows and 0.467 in diffuse rows.

Contamination was not directly measured. The paraphrase audit addresses surface-form sensitivity rather than training-set membership.

## 1.9 Supplementary Note 9: Distribution-quality diagnostics and baselines

This note supports the claim that distribution-mode outputs were not merely fixed uniform or base-rate responses. Distribution-quality diagnostics include Jensen-Shannon divergence, total variation distance, entropy and Brier summaries by source-community disagreement bin and model. Baseline summaries include uniform, global-base-rate and source-majority-oracle comparisons.

These diagnostics assess whether distribution-mode outputs were non-degenerate and item-sensitive. They are support analyses, not a separate distribution-prediction benchmark and not a claim of perfect distribution calibration.

## 1.10 Supplementary Note 10: Normative-certainty secondary analysis

Normative certainty is a secondary descriptive construct. It is not equivalent to estimated source-community agreement and is not a fourth primary endpoint. The corresponding source data are provided in `post_run/analysis_exports/50k/manuscript_tables/table_normative_certainty_50k.csv`.

## 1.11 Supplementary Note 11: Analysis provenance

The inferential source for the Article is the frozen 50k analysis. Earlier cumulative records document collection monitoring and release provenance rather than independent replications. They do not substitute for the final analysis exports.

## 1.12 Supplementary Tables and source-data files

Supplementary Tables 1–8 are provided as accompanying source-data files; this section identifies each file and its role in supporting the Article. File paths are relative to the released

repository/archive root. The listed files are derived analysis/source-data files and do not indicate unrestricted redistribution of raw SCRUPLES anecdotes, rendered prompts, raw provider responses or full run stores.

| Supplementary Table   | What it supports                                                                                                                                                  | Source data                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 1.13 Extended Data figures and source data

Extended Data items provide supporting diagnostics and validity summaries for the main Results. The table below identifies the rendered figures or table source data associated with each item.

| Extended Data item    | What it supports                                                                                                                                     | Source data                                                                                                                                                                                  |

| Extended Data Table 1 | Validity by model/mode and invalid-output summary, including repair fields and exclusion categories.                                                 | post_run/analysis_exports/50k/manuscript_tables/table_validity_by_model_mode_50k.csv;<br>post_run/analysis_exports/50k/manuscript_tables/table_invalid_output_summary_50k.csv                |

### 1.14 Public and restricted materials

Public derived/reviewable materials include manuscript-table CSVs, figure-ready CSVs, rendered figures, run manifests, release-safe prompt templates and schemas, analysis code, endpoint tables, bootstrap confidence intervals, adjusted tests, validity/exclusion summaries, robustness summaries, paraphrase summaries, distribution-quality diagnostics, baseline diagnostics and normative-certainty summaries.

Restricted or carefully shared materials include unredacted source anecdotes, rendered prompts containing anecdote text, raw model/provider responses, full call ledgers with text or API metadata, and full run stores if they contain restricted or mixed material. These materials are shared only under applicable dataset terms, provider terms, privacy/sensitivity constraints and non-redistribution conditions. Restricted verification materials can be provided to editors or reviewers upon reasonable request under appropriate non-redistribution conditions and applicable third-party terms.
