

Study design for testing cross-format uncertainty transfer

a Source-community distributions and bins

Five-label vote distribution

Reference distribution;
not moral truth or universal norms.

Low-consensus is primary; diffuse/no-clear is secondary.

Disagreement-bin logic

High: top label ≥ 0.80
Moderate: 0.65 to < 0.80
Low: 0.50 to < 0.65
Diffuse/no-clear: top label < 0.50

b Same item $\times$ same model across prompt formats

Matched item $\times$ model

same SCRUPLES item
same evaluated model

Distribution mode

estimates five-label probabilities

Verdict/agreement mode

label + agreement estimate

Repeated forced-choice

fresh labels for the same item $\times$ model

Fresh, stateless calls; verdict/agreement does not see the distribution answer.

c Primary endpoint definitions

Agreement surplus

verdict agreement – source support

Distribution-agreement gap

verdict agreement – distribution probability
same model, item and selected label

Sampling compression

source entropy –
repeated-output entropy (bits)

Cleanest cross-format coherence test
